Introduction To Java

- Most people are familiar with Java as a language for Internet applications
- We will study Java as a general purpose programming language
 - The syntax of expressions and assignments will be similar to that of other high-level languages
 - Details concerning the handling of strings and console output will probably be new

Origins of the Java Language

- Created by Sun Microsystems team led by James Gosling in 1991 (now owned by Oracle)
- Originally designed for programming home appliances
 - Difficult task because appliances are controlled by a wide variety of computer processors
 - Team developed a two-step translation process to simplify the task of compiler writing for each class of appliances

Origins of the Java Language

- Significance of Java translation process
 - Writing a compiler (translation program) for each type of appliance processor would have been very costly
 - Instead, developed intermediate language that is the same for all types of processors: Java byte-code
 - Therefore, only a small, easy to write program was needed to translate byte-code into the machine code for each processor

Origins of the Java Language

- Patrick Naughton and Jonathan Payne at Sun Microsystems developed a Web browser that could run programs over the Internet (1994)
 - Beginning of Java's connection to the Internet
 - Original browser evolves into HotJava
- Netscape made its Web browser capable of running Java programs (1995)
 - Other companies follow suit

Objects and Methods

- Java is an object-oriented programming (OOP) language
 - Programming methodology that views a program as consisting of *objects* that interact with one another by means of actions (called *methods*)
 - Objects of the same kind are said to have the same type or be in the same class

Terminology Comparisons

- Other high-level languages have constructs called procedures, methods, functions, and/or subprograms
 - These types of constructs are called methods in Java
 - All programming constructs in Java, including methods, are part of a class

Java Application Programs

- Two common types of Java programs are applications and applets
- A Java application program or "regular" Java program is a class with a method named main
 - When a Java application program is run, the run-time system automatically invokes the method named main
 - All Java application programs start with the main method

Applets

- A Java applet (little Java application) is a Java program that is meant to be run from a Web browser
 - Can be run from a location on the Internet
 - Can also be run with an applet viewer program for debugging
 - Applets always use a windowing interface
- In contrast, application programs may use a windowing interface or console (i.e., text) I/O

A Sample Java Application Program

Display 1.1 A Sample Java Program

```
public class FirstProgram

public static void main(String[] args)

{
    System.out.println("Hello reader.");
    System.out.println("Welcome to Java.");

    System.out.println("Let's demonstrate a simple calculation.");
    int answer;
    answer = 2 + 2;
    System.out.println("2 plus 2 is " + answer);
}

}
```

SAMPLE DIALOGUE I

```
Hello reader.
Welcome to Java.
Let's demonstrate a simple calculation.
2 plus 2 is 4
```

System.out.println

- Java programs work by having things called objects perform actions
 - System.out: an object used for sending output to the screen
- The actions performed by an object are called methods
 - -println: the method or action that the
 System.out object performs

System.out.println

- *Invoking* or *calling* a method: When an object performs an action using a method
 - Also called sending a message to the object
 - Method invocation syntax (in order): an object, a dot (period), the method name, and a pair of parentheses
 - Arguments: Zero or more pieces of information needed by the method that are placed inside the parentheses

```
System.out.println("This is an argument");
```

Variable declarations

- Variable declarations in Java are similar to those in other programming languages
 - Simply give the type of the variable followed by its name and a semicolon

```
int answer;
```

Using = and +

- In Java, the equal sign (=) is used as the assignment operator
 - The variable on the left side of the assignment operator is assigned the value of the expression on the right side of the assignment operator

```
answer = 2 + 2;
```

- In Java, the plus sign (+) can be used to denote addition (as above) or concatenation
 - Using +, two strings can be connected together

```
System.out.println("2 plus 2 is " + answer);
```

Computer Language Levels

- High-level language: A language that people can read, write, and understand
 - A program written in a high-level language must be translated into a language that can be understood by a computer before it can be run
- Machine language: A language that a computer can understand
- Low-level language: Machine language or any language similar to machine language
- Compiler: A program that translates a high-level language program into an equivalent low-level language program
 - This translation process is called compiling

Byte-Code and the Java Virtual Machine

- The compilers for most programming languages translate high-level programs directly into the machine language for a particular computer
 - Since different computers have different machine languages, a different compiler is needed for each one
- In contrast, the Java compiler translates Java programs into byte-code, a machine language for a fictitious computer called the Java Virtual Machine
 - Once compiled to byte-code, a Java program can be used on any computer, making it very portable

Byte-Code and the Java Virtual Machine

- Interpreter: The program that translates a program written in Java byte-code into the machine language for a particular computer when a Java program is executed
 - The interpreter translates and immediately executes each byte-code instruction, one after another
 - Translating byte-code into machine code is relatively easy compared to the initial compilation step
- Most Java programs today run using a Just-In-Time or JIT compiler which compiles a section of byte-code at a time into machine code

Program terminology

- Code: A program or a part of a program
- Source code (or source program): A program written in a high-level language such as Java
 - The input to the compiler program
- Object code: The translated low-level program
 - The output from the compiler program, e.g., Java bytecode
 - In the case of Java byte-code, the input to the Java byte-code interpreter

Class Loader

- Java programs are divided into smaller parts called classes
 - Each class definition is normally in a separate file and compiled separately
- Class Loader: A program that connects the bytecode of the classes needed to run a Java program
 - In other programming languages, the corresponding program is called a *linker*

Compiling a Java Program or Class

- Each class definition must be in a file whose name is the same as the class name followed by . java
 - The class FirstProgram must be in a file named FirstProgram.java
- Each class is compiled with the command javac followed by the name of the file in which the class resides

```
javac FirstProgram.java
```

 The result is a byte-code program whose filename is the same as the class name followed by .class

FirstProgram.class

Running a Java Program

- A Java program can be given the run command (java) after all its classes have been compiled
 - Only run the class that contains the main method (the system will automatically load and run the other classes, if any)
 - The main method begins with the line:

```
public static void main(String[ ] args)
```

 Follow the run command by the name of the class only (no .java or .class extension)

```
java FirstProgram
```

Syntax and Semantics

- Syntax: The arrangement of words and punctuations that are legal in a language, the grammar rules of a language
- Semantics: The meaning of things written while following the syntax rules of a language

Tip: Error Messages

- Bug: A mistake in a program
 - The process of eliminating bugs is called debugging
- Syntax error: A grammatical mistake in a program
 - The compiler can detect these errors, and will output an error message saying what it thinks the error is, and where it thinks the error is

Tip: Error Messages

- Run-time error: An error that is not detected until a program is run
 - The compiler cannot detect these errors: an error message is not generated after compilation, but after execution
- Logic error: A mistake in the underlying algorithm for a program
 - The compiler cannot detect these errors, and no error message is generated after compilation or execution, but the program does not do what it is supposed to do

Identifiers

- *Identifier*: The name of a variable or other item (class, method, object, etc.) defined in a program
 - A Java identifier must not start with a digit, and all the characters must be letters, digits, or the underscore symbol
 - Java identifiers can theoretically be of any length
 - Java is a case-sensitive language: Rate, rate, and RATE are the names of three different variables

Identifiers

- Keywords and Reserved words: Identifiers that have a predefined meaning in Java
 - Do not use them to name anything else

public class void static

- Predefined identifiers: Identifiers that are defined in libraries required by the Java language standard
 - Although they can be redefined, this could be confusing and dangerous if doing so would change their standard meaning

System String println

Naming Conventions

 Start the names of variables, classes, methods, and objects with a lowercase letter, indicate "word" boundaries with an uppercase letter, and restrict the remaining characters to digits and lowercase letters

topSpeed bankRate1 timeOfArrival

 Start the names of classes with an uppercase letter and, otherwise, adhere to the rules above

FirstProgram MyClass String

Variable Declarations

- Every variable in a Java program must be declared before it is used
 - A variable declaration tells the compiler what kind of data (type) will be stored in the variable
 - The type of the variable is followed by one or more variable names separated by commas, and terminated with a semicolon
 - Variables are typically declared just before they are used or at the start of a block (indicated by an opening brace {)
 - Basic types in Java are called *primitive types*

```
int numberOfBeans;
double oneWeight, totalWeight;
```

Primitive Types

Display 1.2 Primitive Types

| TYPE NAME | KIND OF VALUE | MEMORY USED | SIZE RANGE |
|-----------|-------------------------------|-------------|---|
| boolean | true or false | ı byte | not applicable |
| char | single character (Unicode) | 2 bytes | all Unicode characters |
| byte | integer | ı byte | -128 to 127 |
| short | integer | 2 bytes | -32768 to 32767 |
| int | integer | 4 bytes | -2147483648 to 2147483647 |
| long | integer | 8 bytes | -9223372036854775808 to 9223372036854775807 |
| float | floating-point number | 4 bytes | −3.40282347 × 10 ⁺³⁸ to −1.40239846 × 10 ^{−45} |
| double | floating-point number | 8 bytes | ±1.76769313486231570 × 10 ⁺³⁰⁸ to ±4.94065645841246544 × 10 ⁻³²⁴ |

Assignment Statements With Primitive Types

- In Java, the assignment statement is used to change the value of a variable
 - The equal sign (=) is used as the assignment operator
 - An assignment statement consists of a variable on the left side of the operator, and an *expression* on the right side of the operator

```
Variable = Expression;
```

 An expression consists of a variable, number, or mix of variables, numbers, operators, and/or method invocations

```
temperature = 98.6;
count = numberOfBeans;
```

Assignment Statements With Primitive Types

 When an assignment statement is executed, the expression is first evaluated, and then the variable on the left-hand side of the equal sign is set equal to the value of the expression

```
distance = rate * time;
```

Note that a variable can occur on both sides of the assignment operator

```
count = count + 2;
```

 The assignment operator is automatically executed from right-to-left, so assignment statements can be chained

```
number2 = number1 = 3;
```

Tip: Initialize Variables

- A variable that has been declared but that has not yet been given a value by some means is said to be uninitialized
- In certain cases an uninitialized variable is given a default value
 - It is best not to rely on this
 - Explicitly initialized variables have the added benefit of improving program clarity

Tip: Initialize Variables

 The declaration of a variable can be combined with its initialization via an assignment statement

```
int count = 0;
double distance = 55 * .5;
char grade = 'A';
```

 Note that some variables can be initialized and others can remain uninitialized in the same declaration

```
int initialCount = 50, finalCount;
```

Shorthand Assignment Statements

- Shorthand assignment notation combines the assignment operator (=) and an arithmetic operator
- It is used to change the value of a variable by adding, subtracting, multiplying, or dividing by a specified value
- The general form is

```
Variable Op = Expression
```

which is equivalent to

```
Variable = Variable Op (Expression)
```

- The Expression can be another variable, a constant, or a more complicated expression
- Some examples of what Op can be are +, -, *, /, or %

Shorthand Assignment Statements

```
count = count + 2;
count += 2;
sum -= discount;
                     sum = sum - discount;
bonus *= 2;
                     bonus = bonus * 2;
time /=
                     time =
                     time / rushFactor;
rushFactor;
                     change = change % 100;
change %= 100;
amount *=
                     amount = amount *
                     (count1 + count2);
count1 + count2;
```

Assignment Compatibility

 In general, the value of one type cannot be stored in a variable of another type

```
int intVariable = 2.99; //Illegal
```

- The above example results in a type mismatch because a double value cannot be stored in an int variable
- However, there are exceptions to this

```
double doubleVariable = 2;
```

 For example, an int value can be stored in a double type

Assignment Compatibility

 More generally, a value of any type in the following list can be assigned to a variable of any type that appears to the right of it

```
byte-short-int-long-float-double char
```

- Note that as your move down the list from left to right, the range of allowed values for the types becomes larger
- An explicit type cast is required to assign a value of one type to a variable whose type appears to the left of it on the above list (e.g., double to int)
- Note that in Java an int cannot be assigned to a variable of type boolean, nor can a boolean be assigned to a variable of type int

Constants

- Constant (or literal): An item in Java which has one specific value that cannot change
 - Constants of an integer type may not be written with a decimal point (e.g., 10)
 - Constants of a floating-point type can be written in ordinary decimal fraction form (e.g., 367000.0 or 0.000589)
 - Constant of a floating-point type can also be written in scientific (or floating-point) notation (e.g., 3.67e5 or 5.89e-4)
 - Note that the number before the e may contain a decimal point, but the number after the e may not

Constants

- Constants of type char are expressed by placing a single character in single quotes (e.g., 'Z')
- Constants for strings of characters are enclosed by double quotes (e.g., "Welcome to Java")
- There are only two boolean type constants, true and false
 - Note that they must be spelled with all lowercase letters

Arithmetic Operators and Expressions

- As in most languages, expressions can be formed in Java using variables, constants, and arithmetic operators
 - These operators are + (addition), (subtraction),* (multiplication), / (division), and % (modulo, remainder)
 - An expression can be used anyplace it is legal to use a value of the type produced by the expression

Arithmetic Operators and Expressions

- If an arithmetic operator is combined with int operands, then the resulting type is int
- If an arithmetic operator is combined with one or two double operands, then the resulting type is double
- If different types are combined in an expression, then the resulting type is the right-most type on the following list that is found within the expression

```
byte-short-int-long-float-double char ______
```

 Exception: If the type produced should be byte or short (according to the rules above), then the type produced will actually be an int

Parentheses and Precedence Rules

- An expression can be fully parenthesized in order to specify exactly what subexpressions are combined with each operator
- If some or all of the parentheses in an expression are omitted, Java will follow precedence rules to determine, in effect, where to place them
 - However, it's best (and sometimes necessary) to include them

Precedence Rules

Display 1.3 Precedence Rules

Highest Precedence

First: the unary operators: +, -, ++, --, and!

Second: the binary arithmetic operators: *, /, and %

Third: the binary arithmetic operators: + and -

Lowest Precedence

Precedence and Associativity Rules

 When the order of two adjacent operations must be determined, the operation of higher precedence (and its apparent arguments) is grouped before the operation of lower precedence

```
base + rate * hours is evaluated as
base + (rate * hours)
```

 When two operations have equal precedence, the order of operations is determined by associativity rules

Precedence and Associativity Rules

 Unary operators of equal precedence are grouped right-toleft

```
+-+rate is evaluated as + (-(+rate))
```

 Binary operators of equal precedence are grouped left-toright

```
base + rate + hours is evaluated as
(base + rate) + hours
```

 Exception: A string of assignment operators is grouped right-to-left

```
n1 = n2 = n3; is evaluated as n1 = (n2 = n3);
```

Pitfall: Round-Off Errors in Floating-Point Numbers

- Floating point numbers are only approximate quantities
 - Mathematically, the floating-point number 1.0/3.0 is equal to 0.3333333...
 - A computer has a finite amount of storage space
 - It may store 1.0/3.0 as something like 0.333333333, which is slightly smaller than one-third
 - Computers actually store numbers in binary notation, but the consequences are the same: floating-point numbers may lose accuracy

Integer and Floating-Point Division

 When one or both operands are a floating-point type, division results in a floating-point type

```
15.0/2 evaluates to 7.5
```

- When both operands are integer types, division results in an integer type
 - Any fractional part is discarded
 - The number is not rounded

```
15/2 evaluates to 7
```

 Be careful to make at least one of the operands a floatingpoint type if the fractional portion is needed

The % Operator

 The % operator is used with operands of type int to recover the information lost after performing integer division

```
15/2 evaluates to the quotient 715%2 evaluates to the remainder 1
```

- The % operator can be used to count by 2's, 3's, or any other number
 - To count by twos, perform the operation number % 2,
 and when the result is 0, number is even

Type Casting

- A type cast takes a value of one type and produces a value of another type with an "equivalent" value
 - If n and m are integers to be divided, and the fractional portion of the result must be preserved, at least one of the two must be type cast to a floating-point type before the division operation is performed

```
double ans = n / (double)m;
```

- Note that the desired type is placed inside parentheses immediately in front of the variable to be cast
- Note also that the type and value of the variable to be cast does not change

More Details About Type Casting

- When type casting from a floating-point to an integer type, the number is truncated, not rounded
 - (int) 2.9 evaluates to 2, not 3
- When the value of an integer type is assigned to a variable of a floating-point type, Java performs an automatic type cast called a type coercion

```
double d = 5;
```

 In contrast, it is illegal to place a double value into an int variable without an explicit type cast

```
int i = 5.5; // Illegal
int i = (int)5.5 // Correct
```

Increment and Decrement Operators

- The increment operator (++) adds one to the value of a variable
 - If n is equal to 2, then n++ or ++n will change the value of n to 3
- The decrement operator (--) subtracts one from the value of a variable
 - If n is equal to 4, then n-- or --n will change the
 value of n to 3

Increment and Decrement Operators

- When either operator precedes its variable, and is part of an expression, then the expression is evaluated using the changed value of the variable
 - If n is equal to 2, then 2* (++n) evaluates to 6
- When either operator follows its variable, and is part of an expression, then the expression is evaluated using the original value of the variable, and only then is the variable value changed
 - If n is equal to 2, then 2* (n++) evaluates to 4

The Class String

- There is no primitive type for strings in Java
- The class String is a predefined class in Java that is used to store and process strings
- Objects of type String are made up of strings of characters that are written within double quotes
 - Any quoted string is a constant of type String "Live long and prosper."
- A variable of type String can be given the value of a String object

```
String blessing = "Live long and prosper.";
```

Concatenation of Strings

- Concatenation: Using the + operator on two strings in order to connect them to form one longer string
 - If greeting is equal to "Hello ", and javaClass is equal to "class", then greeting + javaClass is equal to "Hello class"
- Any number of strings can be concatenated together
- When a string is combined with almost any other type of item, the result is a string
 - "The answer is " + 42 evaluates to
 "The answer is 42"

Classes, Objects, and Methods

- A class is the name for a type whose values are objects
- Objects are entities that store data and take actions
 - Objects of the String class store data consisting of strings of characters
- The actions that an object can take are called methods
 - Methods can return a value of a single type and/or perform an action
 - All objects within a class have the same methods, but each can have different data values

Classes, Objects, and Methods

- Invoking or calling a method: a method is called into action by writing the name of the calling object, followed by a dot, followed by the method name, followed by parentheses
 - This is sometimes referred to as sending a message to the object
 - The parentheses contain the information (if any) needed by the method
 - This information is called an argument (or arguments)

String Methods

- The String class contains many useful methods for stringprocessing applications
 - A String method is called by writing a String object, a dot, the name of the method, and a pair of parentheses to enclose any arguments
 - If a String method returns a value, then it can be placed anywhere that a value of its type can be used

```
String greeting = "Hello";
int count = greeting.length();
System.out.println("Length is " +
  greeting.length());
```

Always count from zero when referring to the *position* or *index* of a character in a string

Some Methods in the Class String (Part 1 of 8)

Display 1.4 Some Methods in the Class String

int length()

Returns the length of the calling object (which is a string) as a value of type int.

EXAMPLE

After program executes String greeting = "Hello!"; greeting.length() returns 6.

```
boolean equals(Other_String)
```

Returns true if the calling object string and the Other_String are equal. Otherwise, returns false.

EXAMPLE

```
After program executes String greeting = "Hello"; greeting.equals("Hello") returns true greeting.equals("Good-Bye") returns false greeting.equals("hello") returns false
```

Note that case matters. "Hello" and "hello" are not equal because one starts with an uppercase letter and the other starts with a lowercase letter.

Some Methods in the Class String (Part 2 of 8)

Display 1.4 Some Methods in the Class String

boolean equalsIgnoreCase(Other_String)

Returns true if the calling object string and the *Other_String* are equal, considering uppercase and lowercase versions of a letter to be the same. Otherwise, returns false.

EXAMPLE

```
After program executes String name = "mary!";
greeting.equalsIgnoreCase("Mary!") returns true
```

```
String toLowerCase()
```

Returns a string with the same characters as the calling object string, but with all letter characters converted to lowercase.

EXAMPLE

```
After program executes String greeting = "Hi Mary!"; greeting.toLowerCase() returns "hi mary!".
```

Some Methods in the Class String (Part 3 of 8)

Display 1.4 Some Methods in the Class String

String toUpperCase()

Returns a string with the same characters as the calling object string, but with all letter characters converted to uppercase.

EXAMPLE

After program executes String greeting = "Hi Mary!"; greeting.toUpperCase() returns "HI MARY!".

String trim()

Returns a string with the same characters as the calling object string, but with leading and trailing white space removed. Whitespace characters are the characters that print as white space on paper, such as the blank (space) character, the tab character, and the new-line character '\n'.

EXAMPLE

```
After program executes String pause = " Hmm "; pause.trim() returns "Hmm".
```

Some Methods in the Class String (Part 4 of 8)

Display 1.4 Some Methods in the Class String

char charAt(Position)

Returns the character in the calling object string at the *Position*. Positions are counted 0, 1, 2, etc.

EXAMPLE

```
After program executes String greeting = "Hello!"; greeting.charAt(0) returns 'H', and greeting.charAt(1) returns 'e'.
```

String substring(Start)

Returns the substring of the calling object string starting from *Start* through to the end of the calling object. Positions are counted o, 1, 2, etc. Be sure to notice that the character at position *Start* is included in the value returned.

EXAMPLE

```
After program executes String sample = "AbcdefG"; sample.substring(2) returns "cdefG".
```

Some Methods in the Class String (Part 5 of 8)

Display 1.4 Some Methods in the Class String

```
String substring(Start, End)
```

Returns the substring of the calling object string starting from position *Start* through, but not including, position *End* of the calling object. Positions are counted o, 1, 2, etc. Be sure to notice that the character at position *Start* is included in the value returned, but the character at position *End* is not included.

EXAMPLE

After program executes String sample = "AbcdefG"; sample.substring(2, 5) returns "cde".

```
int indexOf(A_String)
```

Returns the index (position) of the first occurrence of the string A_String in the calling object string. Positions are counted 0, 1, 2, etc. Returns -1 if A_String is not found.

EXAMPLE

```
After program executes String greeting = "Hi Mary!"; greeting.indexOf("Mary") returns 3, and greeting.indexOf("Sally") returns -1.
```

Some Methods in the Class String (Part 6 of 8)

Display 1.4 Some Methods in the Class String

```
int indexOf(A_String, Start)
```

Returns the index (position) of the first occurrence of the string A_String in the calling object string that occurs at or after position Start. Positions are counted 0, 1, 2, etc. Returns -1 if A_String is not found.

EXAMPLE

```
After program executes String name = "Mary, Mary quite contrary"; name.indexOf("Mary", 1) returns 6.

The same value is returned if 1 is replaced by any number up to and including 6. name.indexOf("Mary", 0) returns 0. name.indexOf("Mary", 8) returns -1.
```

int lastIndexOf(A_String)

Returns the index (position) of the last occurrence of the string A_String in the calling object string. Positions are counted 0, 1, 2, etc. Returns -1, if A_String is not found.

EXAMPLE

```
After program executes String name = "Mary, Mary, Mary quite so"; greeting.indexOf("Mary") returns 0, and name.lastIndexOf("Mary") returns 12.
```

Some Methods in the Class String (Part 7 of 8)

Display 1.4 Some Methods in the Class String

int compareTo(A_String)

Compares the calling object string and the string argument to see which comes first in the lexicographic ordering. Lexicographic order is the same as alphabetical order but with the characters ordered as in Appendix 3. Note that in Appendix 3 all the uppercase letters are in regular alphabetical order and all the lowercase letters are in alphabetical order, but all the uppercase letters precede all the lowercase letters. So, lexicographic ordering is the same as alphabetical ordering provided both strings are either all uppercase letters or both strings are all lowercase letters. If the calling string is first, it returns a negative value. If the two strings are equal, it returns zero. If the argument is first, it returns a positive number.

EXAMPLE

```
After program executes String entry = "adventure"; entry.compareTo("zoo") returns a negative number, entry.compareTo("adventure") returns 0, and entry.compareTo("above") returns a positive number.
```

Some Methods in the Class String (Part 8 of 8)

Display 1.4 Some Methods in the Class String

int compareToIgnoreCase(A_String)

Compares the calling object string and the string argument to see which comes first in the lexicographic ordering, treating uppercase and lowercase letters as being the same. (To be precise, all uppercase letters are treated as if they were their lowercase versions in doing the comparison.) Thus, if both strings consist entirely of letters, the comparison is for ordinary alphabetical order. If the calling string is first, it returns a negative value. If the two strings are equal ignoring case, it returns zero. If the argument is first, it returns a positive number.

EXAMPLE

```
After program executes String entry = "adventure";
entry.compareToIgnoreCase("Zoo") returns a negative number,
entry.compareToIgnoreCase("Adventure") returns 0, and
"Zoo".compareToIgnoreCase(entry) returns a positive number.
```

String Indexes

Display 1.5 String Indexes

The 12 characters in the string "Java is fun." have indexes 0 through 11.

| J | а | V | а | | i | S | | f | u | n | |
|---|---|---|---|---|---|---|---|---|---|----|----|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |

Notice that the blanks and the period count as characters in the string.

Escape Sequences

- A backslash (\) immediately preceding a character (i.e., without any space) denotes an escape sequence or an escape character
 - The character following the backslash does not have its usual meaning
 - Although it is formed using two symbols, it is regarded as a single character

Escape Sequences

Display 1.6 Escape Sequences

```
\" Double quote.
\' Single quote.
\\ Backslash.
\n New line. Go to the beginning of the next line.
\r Carriage return. Go to the beginning of the current line.
\t Tab. White space up to the next tab stop.
```

String Processing

- A String object in Java is considered to be immutable, i.e., the characters it contains cannot be changed
- There is another class in Java called StringBuffer that has methods for editing its string objects
- However, it is possible to change the value of a String variable by using an assignment statement

```
String name = "Soprano";
name = "Anthony " + name;
```

Character Sets

- ASCII: A character set used by many programming languages that contains all the characters normally used on an Englishlanguage keyboard, plus a few special characters
 - Each character is represented by a particular number
- Unicode: A character set used by the Java language that includes all the ASCII characters plus many of the characters used in languages with a different alphabet from English

Naming Constants

 Instead of using "anonymous" numbers in a program, always declare them as named constants, and use their name instead

```
public static final int INCHES_PER_FOOT = 12;
public static final double RATE = 0.14;
```

- This prevents a value from being changed inadvertently
- It has the added advantage that when a value must be modified, it need only be changed in one place
- Note the naming convention for constants: Use all uppercase letters, and designate word boundaries with an underscore character

Comments

- A line comment begins with the symbols //, and causes the compiler to ignore the remainder of the line
 - This type of comment is used for the code writer or for a programmer who modifies the code
- A block comment begins with the symbol pair /*, and ends with the symbol pair */
 - The compiler ignores anything in between
 - This type of comment can span several lines
 - This type of comment provides documentation for the users of the program

Program Documentation

- Java comes with a program called javadoc that will automatically extract documentation from block comments in the classes you define
 - As long as their opening has an extra asterisk (/**)
- Ultimately, a well written program is selfdocumenting
 - Its structure is made clear by the choice of identifier names and the indenting pattern
 - When one structure is nested inside another, the inside structure is indented one more level

Comments and a Named Constant

```
/**
 1
     Program to show interest on a sample account balance.
     Author: Jane Q. Programmer.
     E-mail Address: janeq@somemachine.etc.etc.
     Last Changed: September 21, 2004.
    */
 6
    public class ShowInterest
 8
 9
         public static final double INTEREST_RATE = 2.5;
10
         public static void main(String[] args)
11
12
             double balance = 100;
13
             double interest: //as a percent
             interest = balance * (INTEREST_RATE/100.0);
14
             System.out.println("On a balance of $" + balance);
15
             System.out.println("you will earn interest of $"
16
17
                                                        + interest):
             System.out.println("All in just one short year.");
18
19
         }
                                 Although it would not be as clear, it is
20 -
                                 legal to place the definition of
21
                                 INTEREST_RATE here instead.
```

SAMPLE DIALOGUE

```
On a balance of $100.0
you will earn interest of $2.5
All in just one short year.
```
